Simple and impossible

Let $u = (u_1, u_2)$. Given u_1 , what is u_2 ?

We need an assumption! Two different standard takes.

Being bounded

Let $u = (u_1, u_2)$ s.t. $\|u\|_{K^{-1}}^2 \leq 1$. Given u_1 , what is u_2 ?

Optimal recovery: $\|u_2 - w\|_{S^{-1}}^2 \leq 1 - \|u_1\|_{(K_{11})^{-1}}^2$

$$w = K_{21}K_{11}^{-1}u_1$$

$$S = K_{22} - K_{21}K_{11}^{-1}K_{12}$$

Let $U = (U_1, U_2) \sim N(0, K)$. Given $U_1 = u_1$, what is U_2 ?

Posterior distribution: $(U_2|U_1 = u_1) \sim N(w, S)$ where

$$w = K_{21}K_{11}^{-1}u_1$$

$$S = K_{22} - K_{21}K_{11}^{-1}K_{12}$$

Kernel functions four ways

Generalizations where K matrix turns into kernel $k(x, y)$:

- Feature maps: $\phi : \mathbb{R}^d \rightarrow \mathcal{H}$, $k(x, y) = \langle \phi(x), \phi(y) \rangle_{\mathcal{H}}$.
Approx scheme: $f(x) \approx w^* \phi(x)$ with $\|w\|_{\mathcal{H}}$ minimal.
- Defining a RKHS norm (equiv to $\|w\|_{\mathcal{H}}$).
- Shape functions: $f(x) \approx \sum_j c_j k(x, x_j)$.
Equivalent to feature map picture (“kernel trick”).
- Covariance for Gaussian process.

RBf / kernel ridge regression / GP differ mainly in regularization, interpretation of error analysis.

Common issues: kernel choice and linear algebra.

Today I will use GP language.

The Big Picture

Gaussian processes (GPs) are

- Key building block for ML and spatio-temporal statistics
- Tightly connected to integral equations, kernel regression
- Straightforward to reason about (just linear algebra)
- But hard to scale to big data (because of dense LA)

Goal today: How to make these methods scale!

Basic ingredient: Gaussian Processes (GPs)

Basic ingredient: Gaussian Processes (GPs)

Our favorite continuous distributions over

$$\mathbb{R}: \quad \text{Normal}(\mu, \sigma^2), \quad \mu, \sigma^2 \in \mathbb{R}$$

$$\mathbb{R}^n: \quad \text{Normal}(\mu, C), \quad \mu \in \mathbb{R}^n, C \in \mathbb{R}^{n \times n}$$

$$\mathbb{R}^d \rightarrow \mathbb{R}: \quad \text{GP}(\mu, k), \quad \mu: \mathbb{R}^d \rightarrow \mathbb{R}, k: \mathbb{R}^d \times \mathbb{R}^d \rightarrow \mathbb{R}$$

More technically, define GPs by looking at finite sets of points:

$$\forall X = (x_1, \dots, x_n), x_i \in \mathbb{R}^d,$$

have $f_X \sim N(\mu_X, K_{XX})$, where

$$f_X \in \mathbb{R}^n, \quad (f_X)_i \equiv f(x_i)$$

$$\mu_X \in \mathbb{R}^n, \quad (\mu_X)_i \equiv \mu(x_i)$$

$$K_{XX} \in \mathbb{R}^{n \times n}, \quad (K_{XX})_{ij} \equiv k(x_i, x_j)$$

When X is unambiguous, we will sometimes just write K .

Basic ingredient: Kernel functions

Call the *kernel* (or *covariance*) function k . Required property:

- **Pos def:** K_{XX} is always positive definite

Often desirable:

- **Stationary:** $k(x, y)$ depends only on $x - y$
- **Isotropic:** $k(x, y)$ depends only on x and $\|x - y\|$

Often want both (sloppy notation: $k = k(r)$).

Common examples (e.g. Matérn, SE) also depend on *hyper-parameters* θ — suppressed in notation unless needed.

Matérn and SE kernels

Observations on kernel matrices

Kernel is *chosen by modeler*

- Choose Matérn / SE for regularity and simplicity
- Rarely have the intuition to pick the “right” kernel
- Common choices are *universal* — can recover anything
 - ... with less data for “good” choice (inductive bias)
- Can combine with DNNs (“deep kernel learning”)

Properties of kernel matrices:

- Positive definite by design, but not well conditioned!
- Weyl: $k(r) \in C^\nu \implies |\lambda_n| = o(n^{-\nu-1/2})$
- SE case: eigenvalues decay (super)exponentially
- Adding $\sigma^2 I$ “wipes out” small eigenvalues

Being Bayesian

Being Bayesian

Now consider prior of $f \sim \text{GP}(\mu, k)$, noisy measurements

$$f_X \sim y + \epsilon, \quad \epsilon \sim N(0, W), \quad \text{typically } W = \sigma^2 I$$

Posterior is $f \sim \text{GP}(\mu', k')$ with

$$\begin{aligned} \mu'(x) &= \mu(x) + K_{xx}c & \tilde{K} &= K_{XX} + W \\ k'(x, x') &= K_{xx'} - K_{xx}\tilde{K}^{-1}K_{xx'} & c &= \tilde{K}^{-1}(y - \mu_X) \end{aligned}$$

The expensive bit: solves with $\tilde{K}$.

Kernel hyper-parameters

How to estimate *hyper-parameters* θ ?

- Bayesian approach? Expensive...
- Usually just do maximum likelihood estimation (MLE)

Log-likelihood function for kernel hypers θ

$$\mathcal{L}(\theta|y) = \mathcal{L}_y + \mathcal{L}_{|K|} - \frac{n}{2} \log(2\pi)$$

where (again with $c = \tilde{K}^{-1}(y - \mu_X)$)

$$\mathcal{L}_y = -\frac{1}{2}(y - \mu_X)^T c, \quad \frac{\partial \mathcal{L}_y}{\partial \theta_i} = \frac{1}{2} c^T \left(\frac{\partial \tilde{K}}{\partial \theta_i} \right) c$$

$$\mathcal{L}_{|K|} = -\frac{1}{2} \log \det \tilde{K}, \quad \frac{\partial \mathcal{L}_{|K|}}{\partial \theta_i} = -\frac{1}{2} \text{tr} \left(\tilde{K}^{-1} \frac{\partial \tilde{K}}{\partial \theta_i} \right)$$

Scalability bottlenecks

Consider n data points

- Straightforward regression: factor $\tilde{K}$ at $O(n^3)$ cost
- Kernel hyper MLE requires multiple $O(n^3)$ ops
 - To compute $\log \det \tilde{K}$ is $O(n^3)$ per step
 - To compute $\text{tr} \left(\tilde{K}^{-1} \frac{\partial \tilde{K}}{\partial \theta_i} \right)$ is $O(n^3)$ per hyper per step

Two possible work-arounds

- Data-sparse factorization methods
- Methods that avoid factorization (e.g. iterative solvers)
 - Q: how to handle determinants and traces?

Simplest data sparse approach

Smooth kernel and long length scales: K nearly rank $m \ll n$

- LL^T = partial pivoted Cholesky (select m inducing points); does *not* require forming K_{XX}
- Solve $(LL^T + \sigma^2 I)c = f_X$ stably by reformulating c as a scaled regularized least squares residual:

$$\text{minimize } \|f_X - Lw\|^2 + \sigma^2 \|w\|^2, \quad c = \sigma^{-2} (f_X - Lw)$$

- Compute $\log \det \tilde{K} = \log \det(L^T L + \sigma^2 I) + 2(n - m) \log \sigma$; similar cheap rearrangement for derivatives.
- Prediction and predictive variance are also cheap.

If K is not low rank, can still use *rank-structured* factorization.

Basic ingredients for “black box” approach

- Fast MVMs with kernel matrices
- Krylov methods for linear solves and matrix functions
- Stochastic estimators: trace, diagonal, and other

Kernel approximations

- Low-rank approximation (via *inducing variables*)
 - Non-smooth kernels, small length scales $\implies$ large rank
 - Only semi-definite
- Sparse approximation
 - OK with SE kernels and short length scales
 - Less good with heavy tails or long length scales
 - May again lose definiteness
- More sophisticated: fast multipole, Fourier transforms
 - Same picture as in integral eq world (FMM, PFFT)
 - Main restriction: low dimensional spaces (2-3D)
- Kernel a model choice — how does approx affect results?

Example: Structured Kernel Interpolation (SKI)

Write $K_{XX} \approx W^T K_{UU} W$ where

- U is a uniform mesh of m points
- K_{UU} has Toeplitz or block Toeplitz structure
- Sparse W interpolates values from X to U

Apply K_{UU} via FFTs in $O(m \log m)$ time.

The power of fast MVMs

Fast MVM with symmetric $\tilde{K} \implies$ try Lanczos!

- Incrementally computes $\tilde{K}Q = QT$ where
 - Q has orthonormal columns
 - Leading k columns span k -dim Krylov space
 - T is tridiagonal
- Building block for
 - Solving linear systems (CG)
 - Approximating eigenvalues
 - Approximating matrix functions: $f(\tilde{K})b$
 - Quadrature vs spectral measure for $\tilde{K}$
- Fast (three-term recurrence) and elegant...
- ... but not forward stable in finite precision

Function application via Lanczos

A computational kernel: $f(\tilde{K})b$

- Run Lanczos from starting vector $b/\|b\|$
- At n steps in exact arithmetic,

$$f(\tilde{K})b = Qf(T)Q^Tb = \|b\|Qf(T)e_1$$

- Truncate at $k \ll n$ steps, use

$$f(\tilde{K})b \approx \|b\|Q_1f(T_{11})e_1$$

- Error analysis hinges on quality of poly approx

$$\min_{f \in P_k} \max_{\lambda \in \Lambda(\tilde{K})} |f(\lambda) - \hat{f}(\lambda)|$$

- Compare: Chebyshev methods just use $[\lambda_{\min}, \lambda_{\max}]$

CG is a special case corresponding to $f(z) = z^{-1}$.

CG solves systems with $\tilde{K}$; problem terms are

$$\mathcal{L}_{|K|} = -\frac{1}{2} \text{tr} \left(\log \tilde{K} \right) \quad \frac{\partial \mathcal{L}_{|K|}}{\partial \theta_i} = -\frac{1}{2} \text{tr} \left(\tilde{K}^{-1} \frac{\partial \tilde{K}}{\partial \theta_i} \right)$$

Q: How do we parley fast MVMs into trace computations?

Tractable traces

Stochastic trace estimation trick:

- $z \in \mathbb{R}^n$ has independent random entries
- $\mathbb{E}[z_i] = 0$ and $\mathbb{E}[z_i^2] = 1$

Then

$$\mathbb{E}[z^T A z] = \sum_{i,j} a_{ij} \mathbb{E}[z_i z_j] = \text{tr}(A).$$

NB: $\mathbb{E}[z \odot A z] = \text{diag}(A)$.

Standard choices for the probe vector z :

- Hutchinson: $z_i = \pm 1$ with probability 0.5
- Gaussian: $z_i \sim N(0, 1)$

See Avron and Toledo review, JACM 2011.

Putting it together

For each probe vector z until error bars small enough:

- Run Lanczos from $z/\|z\|$
- Use Lanczos to estimate $\tilde{K}^{-1}z$ and $\log(\tilde{K})z$
- Dot products yield estimators:

$$\mathcal{L}_{|K|} = -\frac{1}{2}\mathbb{E}\left[z^T \log(\tilde{K})z\right]$$
$$\frac{\partial \mathcal{L}_{|K|}}{\partial \theta_i} = -\frac{1}{2}\mathbb{E}\left[(\tilde{K}^{-1}z)^T \left(\frac{\partial \tilde{K}}{\partial \theta_i}z\right)\right]$$

Cost per probe:

- One Lanczos process
- One matvec per parameter with derivative

Quite effective in practice! And amenable to preconditioning.

Example: Rainfall

Example: Rainfall

Map generated by NOAA's National Climatic Data Center, 2007

0 698mi

Example: Rainfall

Method	n	m	MSE	Time [min]
Lanczos	528k	3M	0.613	14.3
Scaled eigenvalues	528k	3M	0.621	15.9
Exact	12k	-	0.903	11.8

- Data: Hourly precipitation data at 5500 weather stations
- Aggregate into daily precipitation
- Total data: 628K entries
- Train on 100K data points, test on remainder
- Use SKI with 100 points per spatial dim, 300 in time
- Comparison: scaled eigenvalues approx, exact solve

Example: Hickory data

Can build other stochastic processes via GPs

- Example: Log-Gaussian Cox process model
 - Models count data (e.g. events in spatial bins)
 - Poisson conditional on intensity function
 - Log intensity drawn from a GP
- Laplace approximation for posterior
- Data set is point pattern of 703 hickory trees in Michigan

Example: Hickory data

Figure 1: Prediction by different methods on the Hickory dataset.

Method	s_f	ℓ_1	ℓ_2	$-\log p(y \theta)$	Time [s]
Exact	0.696	0.063	0.085	1827.56	465.9
Lanczos	0.693	0.066	0.096	1828.07	21.4
Scaled eigs	0.543	0.237	0.112	1851.69	2.5

Table 1: Hyper-parameters recovered by different methods

Teaser example: Applications with derivatives

Recovering the Stanford bunny model from 25K noisy normals.
